

CS4248: Natural Language Processing

Lecture 2 — Strings & Words

Recap of Week 01

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

• Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

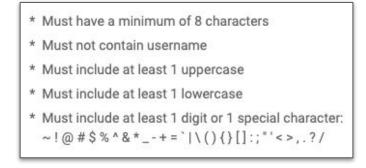

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Regular Expressions

- Regular Expression Definition
 - Search pattern used to match character combinations in a string
 - Pattern = sequence of characters
- Common applications
 - Parse text documents to find specific character patterns
 - Validate text to ensure it matches predefined patterns
 - Extract, edit, replace, delete substrings matching a pattern
- Two basic search approaches
 - Default: match only <u>first</u> occurrence of pattern
 - Global search: match <u>all</u> occurrences of pattern (assumed in most following examples)

Example: password validation

Basic Patterns

- Fixed patterns
- floor → My block has 15 floors, and I live on floor 5.
 - 5 \rightarrow My block has 15 floors, and I live on floor 5.
- blocks → My block has 15 floors, and I live on floor 5.

• Special characters (metacharacters)

Character	Explanation
•	matches any character except line breaks
^	match the start of a string
\$	match the end of a string
I	matches RegEx either before or after the symbol (e.g., floor floors)
\b	matches boundary between word and non-word

Character Classes

- Character class
 - Defines set of valid characters
 - Enclosed using "[...]"
 - Can be negated: "[^...]"
 - $[0-9][0-9] \rightarrow My \ block \ has \ 15 \ floors, \ and \ I \ live \ on \ floor \ 5.$ (match all sequences of 2 digits)
 - [.,;:] → My block has 15 floors, and I live on floor 5. (match all sequences of length 1 that are either a period, comma, etc.)
 - $[^a-z] \rightarrow My$ block has 15 floors, and I live on floor 5.

(match all sequences of length 1 that are not a lowercase letter)

Predefined Character Classes

• Common character classes with their own shorthand notation (i.e., metacharacters)

Class	Alternative	Explanation
\d	[0-9]	matches any digit
(ע	[^0-9]	matches any non-digit
\s	[\n\r\t\f]	matches any whitespace character
\s	[^ \n\r\t\f]	matches any non-whitespace character
\w	[a-zA-Z0-9_]	matches any word character
\w	[^a-zA-Z0-9_]	matches any non-word character

Repetition Patterns

- Very common: patterns with flexible lengths, e.g.:
 - All numbers with more than 2 digits
 - All words with less than 5 characters
- Repetition patterns metacharacters

Pattern	Explanation
+	1 or more occurrences
*	0 or more occurrences
?	0 or 1 occurrences
{n}	exactly n occurrences
{1,u}	between 1 and u occurrences; can be unbounded: {1, } or {,u}

Repetition Patterns — Examples

 $\d \{2,\}$ \rightarrow My block has 15 floors, and I live on floor 5. (match all numbers with 2 or more digits)

- \d+ → My block has 15 floors, and I live on floor 5. (match all numbers with 1 or more digits)
- $b w \{2, 4\} b \rightarrow My block has 15 floors, and I live on floor 5. (match words with 2 to 4 characters)$
- \b[Ff]loor[s]?\b →
- My block has 15 floors, and I live on floor 5.

(match occurrences of "floor", either capitalized or not, either in singular or plural)

Groups

Quick quiz: In which case(s) would the RegEx below fail to correctly match an email address?

- Groups: Organizing patterns into parts
 - Groups are enclosed using "(...)"
 - While whole expression must match, groups are captures individually (a match is no longer a string but a tuple of strings, on for each group)
 - Groups can be nested, e.g., (...(...)...((...))...) (order of groups depends on the order in which the groups "open")

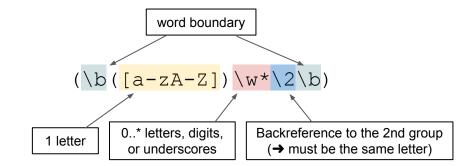

Send an email to alice@example.org for more information.

Match:	user@example.org
Group #1:	alice
Group #2:	example.org

Backreferences

Quick quiz: Can the same be achieved using only 1 group?

- Reference groups within a RegEx
 - Find repeated patterns (see example below)
 - Support only partial replacement of matches
- Example:
 - "My mom said I need to pass this test."
 - Goal: Find all words that start and end with the same letter

Match:	тот
Group #1:	тот
Group #2:	m

Match:	test
Group #1:	test
Group #2:	t

Lookarounds

- Special groups assertions
 - Match like any other group, but do not capture the match
 - 2 types: lookaheads and lookbehinds
 - 2 forms of assertion: positive and negative

	Туре	Example
(?=)	positive lookahead	$A(?=B) \rightarrow$ finds expr. A but only when followed by expr. B
(?!)	negative lookahead	A(?!B) \rightarrow finds expr. A but only when not followed by expr. B
(?<=)	positive lookbehind	$(? <= B) \land \Rightarrow$ finds expr. A but only when preceded by expr. B
(?)</td <td>negative lookbehind</td> <td>(?<!--B) A → finds expr. A but only when not preceded by expr. B</td--></td>	negative lookbehind	(? B) A → finds expr. A but only when not preceded by expr. B</td

Lookarounds — Example

- Positive lookahead
 - "Paying 10 SGD for 1 kg of chicken seems fair."
 - Goal: Extract all kg values (numbers followed by the unit kg)

 \rightarrow

 $d+(?=\s*kg)$

"Paying 10 SGD for 1 kg of chicken seems fair.

→ "Paying 10 SGD for 1.5 kg of chicken seems fair.

"Paying 10 SGD for 1,500.00 kg of chicken seems fair.

"Paying 10 SGD for 1 kg of chicken seems fair.

[0-9.,]*[0-9]+(?=\s*kg)

"Paying 10 SGD for 1,500.00 kg of chicken seems fair.

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

Pre-Lecture Activity from last week

Pre-Lecture Activity for Next Week

• Assigned Task (due before Jan 20)

Post a 1-2 sentence answer to the following question into the L1 Discussion forum (you will find the thread on Canvas > Discussion > Week 2 (L1))

"What is the relationship between a Finite State Machine and Regular Expressions?"

Side notes:

- This task is meant as a warm-up to provide some context for the next lecture
- No worries if you get lost; we will talk about this in the next lecture
- You can just copy-&-paste others' answers but this won't help you learn better

Google said they are the same. ChatGPT said there are totally different. Me myself think that regular expression could be drawn as state machine using criteria together with their groupings as state transitions. So deadend, spider trap any thing can happen in state graph in both deterministic and non. However, parsing a string to regex would be deterministic at some point.

Regular Expressions can be used to represent a Finite State Machine via a regular expression pattern. A regular expression pattern can be converted into a Finite State Machine directed graph that enable us to perform character matching and understanding a word's morphology.

References:

- <u>https://ljvmiranda921.github.io/notebook/2022/10/07/finite</u>state-automata/ ⊟→

- https://www.cs.drexel.edu/~johnsojr/2006-

07/winter/cs360/lectures/lec2.html

YC

Regular expressions describe finite state machines, where instead of actions, we have individual letters/characters. However, FSM implementations of Regex cannot do capture groups, and in general, offer different conveniences/challenges in implementation as compared to direct Regex implementations.

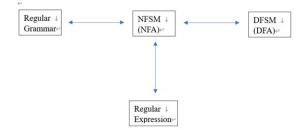

References:

https://bakalian.cs.umd.edu/assets/notes/fa.pdf ⊟

FSM is a mathematical model of computation. According to the different transfer functions, it can be divided into Deterministic Finite Automaton(DFA) and Nondeterministic Finite Automaton(NFA).

LH

Regular expressions are based on the theory of automata. After the user writes the regular expression, the corresponding FSM can be constructed through the regular expression. (This FSM may be DFA or NFA)

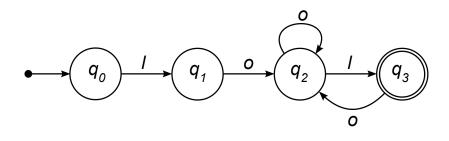

Relationship to Finite State Automata

• Equivalence

 Regular Expressions describe Regular Languages (most restricted types of languages w.r.t Chomsky Hierarchy)

Regular Language = language accepted by a FSA

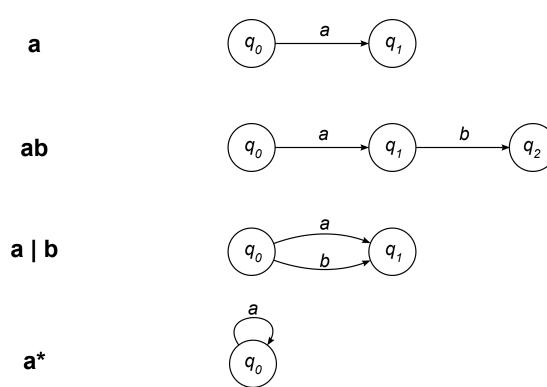

Example: FSA that accepts the Regular Language described by the Regular Expression **I(o+I)+**

Regular Expression
l(o+l)+
Regular Language
$\{$ IoI, loool, lolol, looolol, $\}$
Chomsky Hierarchy (Source: <u>Wikipedia</u>)
recursively enumerable
context-sensitive context-free regular

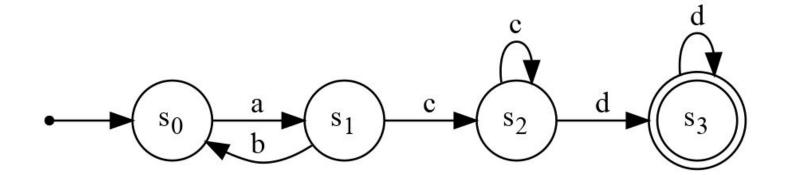

Relationship to Finite State Automata

• Basic equivalences

🏃 🏃 🏃 In-Lecture Activity (5 mins)

- Task: Find the RegEx describing the FSA below
 - Post your RegEx to Canvas > Discussions
 (individually or as a group; include all group members' names in the post)
 - Optional: There is more than one correct answer → Why?

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

• Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

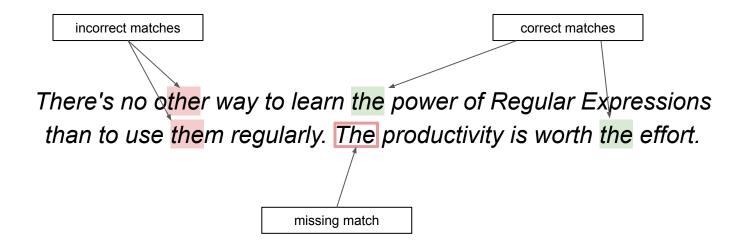

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Error Types — What Can Go Wrong

Quick quiz: What would be a better RegEx for this task?

- Example: Find all occurrences of article "the"
 - Naive approach: "the" (fixed pattern)

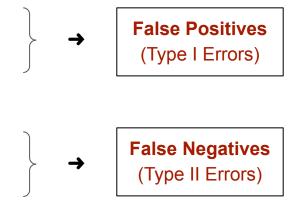

Error Types

• 2 basic types of errors

Matching strings that we should <u>not</u> have matched (e.g., other, theology, weather, bathe, mother)

<u>Not</u> matching things that we should have matched (e.g., *THE*)

Error Types — Observations

- Many contexts deal with these 2 types of errors, e.g.:
 - Medical testing (e.g., ART test is positive but person is not infected with COVID → false positive)
 - Information retrieval (e.g., a Web search is missing a relevant page → false negative)
 - Document classification (e.g., an abusive tweet has be classified as positive → false positive)

Reducing errors false negative false positive

- Both error types not always equally bad (infected person tests negative vs. healthy person test positive)
- Reducing False Positives and False Negatives often in conflict (reducing False Positives often increases False Negatives, and vice versa)

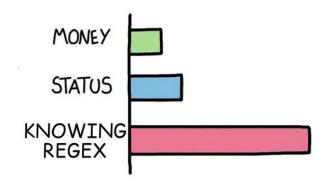

Regular Expressions — Summary

- Know their powers
 - Extremely useful tool for many (low-level) text processing tasks (e.g., data preprocessing, tokenization, normalization)
 - Important skill for anyone working with strings or text

• Know their limitations

- Regular Expressions represent hard rules
- Higher-level text processing task generally require statistical models ("soft" rules)
- → Machine Learning classifiers

WHAT GIVES PEOPLE FEELINGS OF POWER

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

• Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

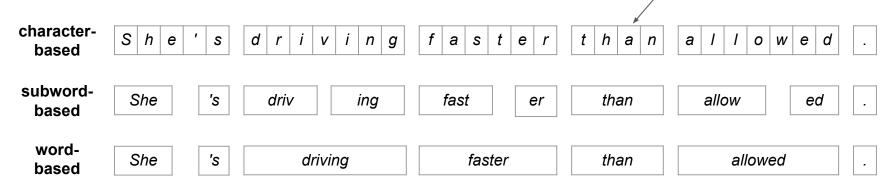

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Tokenization

● Tokenization: splitting a string into tokens → vocabulary (set of all unique tokens)

- Token = character sequence with a semantic meaning (typically: words, numbers, punctuation — but may differ depending on applications)
- Very important for step for most NLP algorithms (tokenization errors quickly propagate up → "garbage in, garbage out")
- 3 basic approaches

Character-based tokenization trivial (e.g., using Regex: .)

Tokenization — Word-Based

- 2 intuitive approaches (solved using RegEx)
 - Match all words, numbers and punctuation marks
 - punctuation marks $\rightarrow \w+|\d+|[, ;:]$
 - Match boundaries between "words" and "non-words" → $(?=\setminus W) | (?<=\setminus W)$

$w+|d+|[,.;:] \rightarrow NLP$ is fun, and there is so much to learn in 13 weeks.

$(?=\setminus W) | (?<=\setminus W) \rightarrow NLP | is fun, and there | is so much to learn in 13 weeks.$

Tokenization — It Quickly Gets Tricky

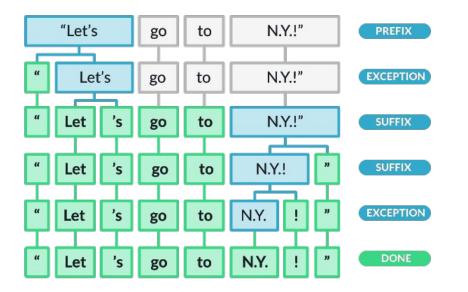

- Multiword phrases
 → I just came back from New York City.
- Common contractions \rightarrow *I'm not home, so don't call.*
 - → NLP is a well-defined but non-trivial topic.
- Acronyms, names, etc. \rightarrow *I* watched a C++ documentary on T.V.
- Special tokens

Hyphenations

→ My email is chris@nus.comp.nus.sg :o)

RegEx used:

Example: spaCy Tokenizer

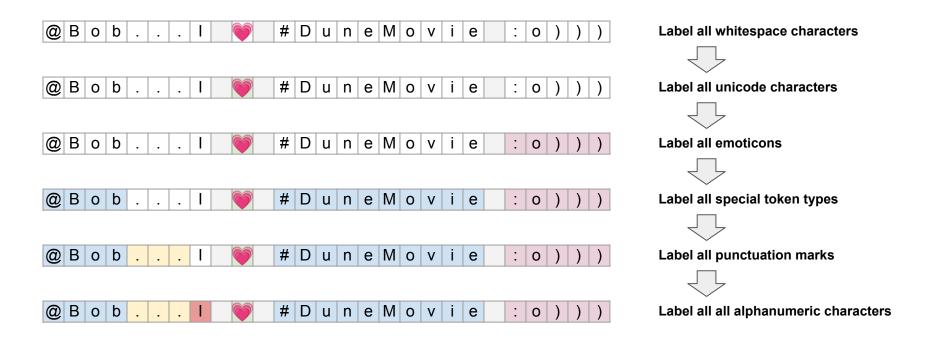

- (1) Split string on whitespace characters
- (2) From left to right, recursively check substrings:
 - Does substring match an exception rule? (e.g., "don't" → "do", "n't", but keep "U.K.")
 - Can a prefix, suffix or infix be split of? (e.g., commas, periods, quotes, hyphens)

Substring checks based on

- Regular Expressions
- Hand-crafted rules / patterns

Example: Chris's Tokenizer

Sequential labeling of characters

→ Tokens = Substrings with adjacent characters with the same labels

Tokenization — Language Issues

- French
 - Different uses of apostrophes and hyphens (compared to English)

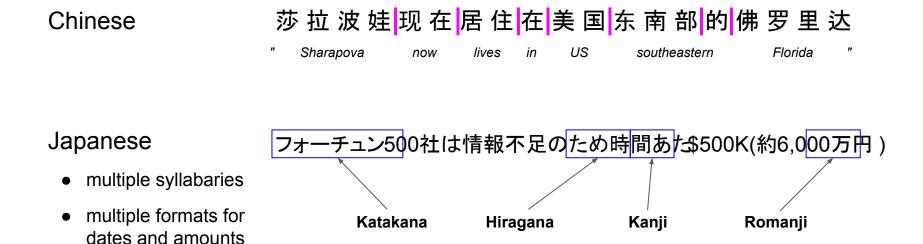

- German
 - Very common: compound nouns

Arbeiterunfallversicherungsgesetz "worker injury insurance act"

→ important: compound splitter

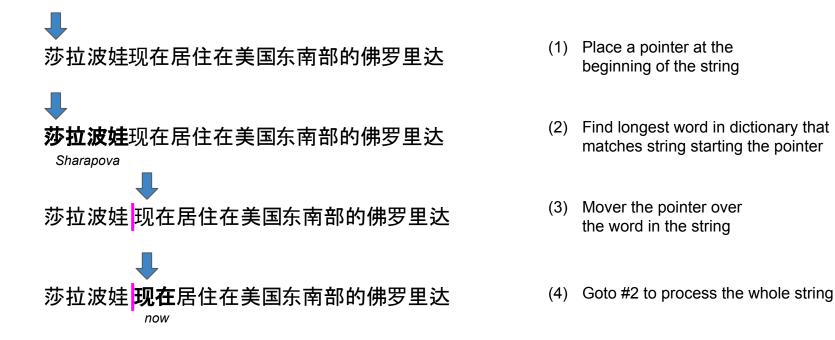

Tokenization — Language Issues

Languages without whitespaces separating words

Tokenization — Word Segmentation of Chinese Text

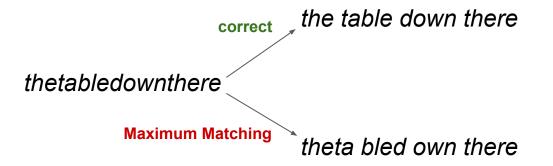

Baseline algorithm: Maximum Matching

Tokenization — Maximum Matching

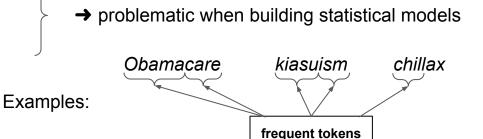

• Surprisingly good performance on Chinese text (even better performance with probabilistic methods or extensions)

• Generally does not work for English text

Tokenization — Subword-Based

- Subword-based tokenization
 - So far: a priori specification of rules (e.g., RegEx) what constitutes valid tokens
 - Now: use data to specify how to tokenize
- Why do we want to do this?
 - Out Of Vocabulary (OOV) words (word/token an NLP model has not seen before)
 - Very rare words in corpus

→ Goal: Split OOV and rare words into (some) known & frequent tokens

Tokenization — Subword-Based

- Different algorithms for subword tokenization
 - <u>Byte-Pair Encoding (BPE)</u>, Unigram Language Model Tokenization, WordPiece, etc.

• Different approaches, similar 2-parts setup

(1) Token Learner

Takes raw training corpus and induces a vocabulary (i.e., set of tokens)

(2) Token Segmenter

Takes a raw text and tokenizes it according to vocabulary

Quick quiz: What happens if k=0 or k=∞ ?

Corpus:

"low low low low lower lower newest newest newest newest newest newest widest widest longer"

special end-of-word token Initialize vocabulary (e.g., {'d', 'e', 'g', 'i', 'l', 'n', 'o', 'r', 's', 't', 'w', [_])

REPEAT

Find the 2 tokens most frequently adjacent to each other (e.g., 'e', 's')

Add a new merged token 'es' to vocabulary

Replace every adjacent 'e' 's' in corpus with 'es'

UNTIL k merges have been done

parameter of algorithm

6 n e w e s t _ 5 l o w _ 3 w i d e s t _ 2 l o w e r _ 1 o n g e r _

corpus representation

vocabulary

merges

(e, s), (es, t), (est, _), (l, o), (lo, w)

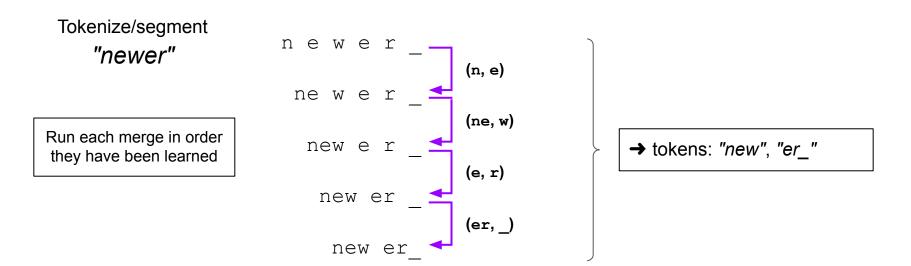

most frequent pair: n & e (6 occurrences)

- vocabulary d, e, g, i, l, n, o, r, s, t, w, _, es, est, est_, lo, low, ne
 - merges (e, s), (es, t), (est, _), (l, o), (lo, w), (n, e)
 - \bigcirc
- vocabulary d, e, g, i, l, n, o, r, s, t, w, _, es, est, est_, lo, low, ne, new
 merges (e, s), (es, t), (est, _), (l, o), (lo, w), (n, e), (ne, w)
 - \bigtriangledown
- vocabulary d, e, g, i, l, n, o, r, s, t, w, _, es, est, est_, lo, low, ne, new, newest_
 merges (e, s), (es, t), (est, _), (l, o), (lo, w), (n, e), (ne, w), (new, est_)

Tokenization — BPE Token Segmenter

vocabulary	d, e, g, i, l, n, o, r, s, t, w, _, es, est, est_, lo, low, ne, new, newest_,
	low_,er,er_,wi,wid,widest_,lower_,lon,long,longer_
merges	(e, s), (es, t), (est, _), (l, o), (lo, w), (n, e), (ne, w), (new, est_), (low, _), (e, r),

(er, _), (w, i), (wi, d), (wid, est_), (low, er_), (lo, n), (lon, g), (long, er_)

Tokenization — Summary

- Tokenization as low-level NLP task
 - Challenges: important, non-trivial, language-dependent
 - Particularly tricky for informal language (e.g., social media)

• 3 basic approaches

- Character-based (trivial to do but often not suitable individual characters generally carry no semantic meaning)
- Word-based (a priori specification of rules; language-dependent; problem: OOV/rare words)
- Subword-based (tokenization learned from data tokens are often morphemes!)
- Practical consideration (when using off-the-shell word-based tokenizers)
 - What is my type of text (e.g., formal or informal)? Are there special tokens (e.g., URLs, hashtags)?
 - Try and assess different tokenizers very, very last resort: write your own tokenizer

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Normalization

• Goal: Convert text into a canonical (standard) form

- Remove noise / "randomness" from text
- Affects characters, <u>words</u>, sentences, documents

• Implicit definition of equivalence classes

Suitable normalization steps depend on task/application

Alternative to equivalence classes: **asymmetric expansion** Example: Web Search (utilize case of search terms)

Entered term		Searched terms
window	→	window, windows
windows	→	Windows, windows, window
Windows	→	Windows

Raw	Normalized
Germany GERMANY	germany
USA U.S.A US of A	USA
tonight tonite 2N8	tonight
connect connects connected connecting connection	connect
:) :-) :0)	smile

Normalization — Case Folding

- When to fold?
 - Common application: Information Retrieval (e.g., Web search where must users type only in lowercase anyway)
 - Potential problems: Bush vs. bush, MOM vs. mom, Cloud vs. cloud, etc. (potential exception: upper case word in mid sentence?)

• When NOT to fold?

- NLP tasks where case of letters or words are important features
- Examples: Named Entity Recognition, Machine Translation

They sent **us** a card from the **US** during their vacation. Distinction important for NER and MT!

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Normalization — Stemming & Lemmatization

• Motivating example:

"dogs make the best friends" vs. "a dog makes a good friend"

→ Very similar semantics but (very) different syntax

Common reasons for variations of the same word

- Singular vs. plural form (mainly of nouns)
- Different tenses of verbs
- Comparative/superlative of adjectives

→ Can we normalize words to abstract from such variations?

Normalization — Stemming

- Idea of Stemming
 - Reduce words to their stem
 - Approach: crude chopping of affixes based on rules (→ language dependent)
 - Different stemmers apply different rules

• Characteristics

- Pro: fast + no lexicon required
- Con: stemmed word not necessarily a proper word (i.e., not in dictionary)

Examples

(alternatives reflect results from different stemmers)

Raw	Stemmed
cats	cat
running	run
phones	phon(e)
presumably	presum
crying	cry/cri
went	went
worse	wors
best	best
mice	mic(e)

Normalization — Stemming: Porter Stemmer

- Porter Stemmer most common stemmer for English text
 - Simple, efficient + very good results in practice
- Series of rewrite rules that run in a cascade
 - Output of each pass is fed is input to the next pass
 - Stemming steps if a pass yields no more changes

	sses → ss	e.g.: possesses → possess, classes → class
	tional \rightarrow tion	e.g., optional \rightarrow option, fictional \rightarrow function
	ies → i	e.g., cries \rightarrow cri, tries \rightarrow tri
stem must contain vowel ——	►(*v*)ing → ε	e.g.: sing \rightarrow sing, singing \rightarrow sing, talking \rightarrow talk
stem must contain >1 chars ——	⊳(m>1)ement → ε	e.g., replacement \rightarrow replac, cement \rightarrow cement

Normalization — Lemmatization

- Idea of Lemmatization
 - Reduce inflections or variant forms to base form
 - Find the correct dictionary headword form
 - Differentiates between word forms: nouns (N), verbs (V), adjectives (A)

Raw	Lemmatized (N)	Lemmatized (V)	Lemmatized (A)
running	running	run	running
phones	phone	phone	phones
went	went	go	went
worse	worse	worse	bad
mice	mouse	mice	mice

Normalization — Lemmatization: Characteristics

• Pros

- Lemmatized words are proper words (i.e., dictionary words)
- Can normalize irregular forms (e.g., went \rightarrow go, worst \rightarrow bad)

• Cons

- Requires curated lexicons / lookup tables + rules (typically)
- Requires Part-of-Speech tags for correct results
- Generally slower as stemming

Normalization — Stemming & Lemmatization

• Back to our motivating example

Raw:	"dogs make the best friends"	"a dog makes a good friend"
Stemmed:	"dog make the best friend"	"a dog make a good friend"
Lemmatized:	"dog make the good friend"	"a dog make a good friend"

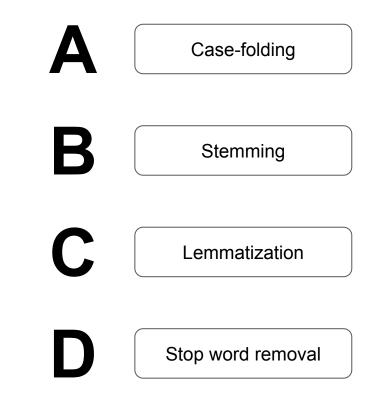

Normalization — Final Words

- Canonical form also effects tokenization, e.g.: Penn Treebank Tokenizer
 - Separate out clitics (e.g., $doesn't \rightarrow does n't$; $John's \rightarrow John 's$)
 - Keep hyphenated words together
 - Separate out all punctuation symbols
- Other common normalization steps
 - Removal of stopwords (e.g., a, an, the, not, and, or, but, to, from, at)
 - Removal of non-standard tokens (e.g., URs, emojis, emoticons)

■ ...

In-Lecture Activity

Which preprocessing step would arguably affect **sentiment analysis** negatively?

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Sentence Segmentation

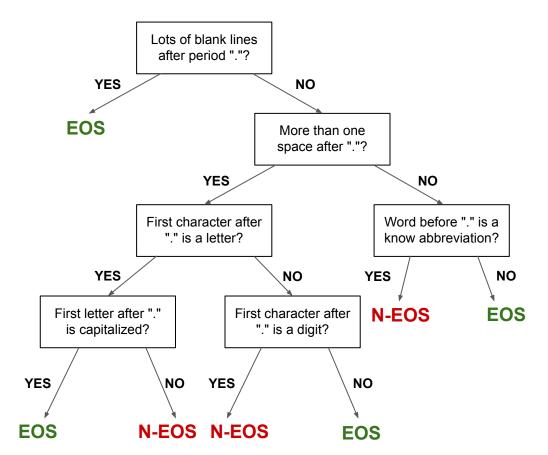

- Sound like a simple task but...
 - Period "." can be quite ambiguous (e.g., "1.25", "U.S.A.", "Dr.") "?", "!" relatively unambiguous
 - Poor punctuation in informal text (common: missing whitespaces, missing capitalization)
 - → RegEx for segmenting sentences quickly become very complex

Example RegEx: (?<!\w\.\w.) (?<! $[A-Z] [a-z] \.)$ (?<=\.|\?) \s (Source: Stackoverflow)

- Alternative: binary classifier
 - Consider each period "." in a text
 - Classify: EndOfSentence or NotEndOfSentence
 - → Possible approaches: handwritten rules, set of RegEx, machine learning

Example: Simple Rules (represented as a binary Decision Tree)

Quick quiz: What are some common cases where this classifier would fail?

Many Other Features Conceivable

- Example: numerical features
 - length of word before / after period "."
 - Distance (in #chars) to next punctuation mark
 - Probabilities derived from a dataset
 (e.g., probability of with "." occurs at the end of sentence)

Side note: In informal text (e.g., social media) people often use emoticons or emojis to separate sentences, making this task even more complicated.

• Word error handling

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

2

Spelling Errors

1. Non-word error detections

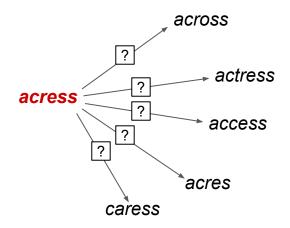

- Basically, word is not found in dictionary
- Example: detecting graffe (misspelling of giraffe)

2. Isolated-word error correction

- Consider word in isolation (i.e., without surrounding words)
- Example: correcting *graffe* to *giraffe*

3. Context-sensitive error detection & correction

- Consider surrounding words to detect and correct errors
- Important for "wrong" words that a spelled correctly
- Examples: there vs. three, dessert vs. desert, son vs. song

Spelling Errors — Common Patterns

- Observation
 - Most misspelled words in typewritten text are single-error
 - Damerau (1964): 80%, Peterson (1986): 93-95%
- Single-error misspellings
 - Insertion (e.g., *acress* vs. *acres*)
 - Deletion (e.g., *acress* vs. *actress*)
 - Substitution (e.g., *ac<u>r</u>ess* vs. *ac<u>c</u>ess)*
 - Transposition (e.g., <u>acress</u> vs. <u>caress</u>)

For non-word errors:

- → Good candidates are orthographically similar
- → Minimum Edit Distance

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA

- Noisy Channel Model

2

Minimum Edit Distance (MED)

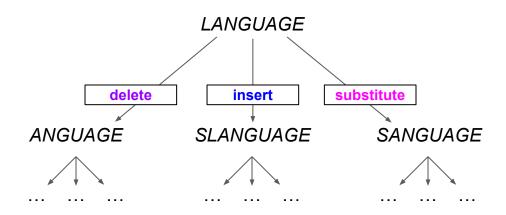

- Minimum Edit Distance between 2 strings s_1 and s_2
 - Minimum number of allowed edit operations to transform s_1 into s_2
 - Allowed edit operations: Insertion, Deletion, Substitution, Transposition -

Not covered here to keep examples simple

- Example
 - $s_1 = "LANGUAGE"$
 - $s_2 = "SAUSAGE"$

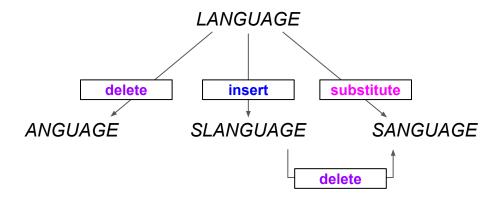

- MED if all operations cost 1 \rightarrow 4
- MED if Substitution costs 2, Insertion 1, Deletion 1 → 5

- Problem formulation: Find a path (i.e., sequence of edits) from start string to final string
 - Initial state: the word being transformed (e.g., "LANGUAGE")
 - Target state: the word being transformed into (e.g., "SAUSAGE")
 - Operators: insert, delete, substitute
 - Path cost: aggregated costs of all edits

- → Potentially huge search space
- → Naive navigation of all path impractical

- Observations
 - Many distinct paths end up in the same state

- → No need to keep track of all paths
- → Only important: "cheapest" path to each revisited state (best in terms of costs, not just number of operations!)
- → Solve using Dynamic Programming

solving problems by combining solutions to subproblems

- Input: 2 strings
 - $\bullet \quad \text{Source string } X \text{ of length } n$
- Target string Y of length m

 first i chars of X
 first j chars of Y

 Define D(i, j) as MED between X[0..i] and Y[0..j]

→ MED between X and Y is thus D(n,m)

- Bottom-up approach of Dynamic Programming
 - Compute D(i, j) for small i, j (base cases)
 - **Compute** D(i, j) for larger *i*, *j* based on previously computes D(i, j) for smaller *i*, *j*

• Initialization of bases cases

- \blacksquare D(i,0) = i (getting from X[0..i] to empty target string requires i deletions)
- D(0, j) = j (getting from empty source string to Y[0..j] requires j insertions)
- For $0 < i \le n$ and $0 < j \le m$

$$D(i,j) = \min \begin{cases} D(i-1,j) + 1 & \text{Delete} \\ D(i,j-1) + 1 & \text{Insert} \\ D(i-1,j-1) + \begin{cases} 2, & if X[i] \neq Y[j] \\ 0, & if X[i] = Y[j] \end{cases} \text{Substitute} \end{cases}$$

Assumptions for costs
Insert: 1
Delete: 1
Substitute: 2
→ Levenshtein MED

analysis
O(nm)
O(nm)

Minimum Edit Distance — Backtrace & Alignments

- Current limitation
 - Base algorithm only returns the MED
 - Often important: alignment between strings

How do we get this?

• Keep track of backtrace

- Remember from which "direction" we entered a new cell
- At the end, trace path from upper right corner to read of alignment

Keep set of pointers for each i, j

Small extension to base algorithm:

$$PTR(i,j) = \begin{cases} \texttt{LEFT} & \texttt{Insert} \\ \texttt{DOWN} & \texttt{Delete} \\ \texttt{DIAG} & \texttt{Substitute} \end{cases}$$

Note: Backtraces are generally not unique → different alignments for the same MED possible

🏃 🏃 🏃 In-Lecture Activity (5 mins)

- Task: Compute the MED and alignment between "NUS" and "TRUST"
 - Post your MED (Levenshtein) and alignment to Canvas > Discussions (individually or as a group – add all group members' names to the post)

S	3					
U	2					
Ν	1					
#	0	1	2	3	4	5
	#	Т	R	U	S	Т

- Try to complete the table for this task (probably not needed as the words are very short)
- Some of you can share their solution

Example alignment (but bad one!)
NUS****
***TRUST

In-Lecture Activity

• Solution

S	3	$\swarrow \leftarrow \downarrow 4$	$\swarrow \leftarrow \downarrow 5$	$\downarrow 4$	$\swarrow 3$	$\leftarrow 4$

Minimum Edit Distance — Other Uses in NLP

• Evaluating Machine Translation and speech recognition

e.g., How similar are 2 translations?

Reference:	Spokesman 🕻	confirms	*	senior	government	t adviser	was	shot	*
	I	- I	1		1				
Prediction:	Spokesman	said	the	senior	*	adviser	was	shot	dead

Named Entity Extraction and Entity Coreference

"We stayed at the * Merchant Court prior to a cruise" "The Swissotel Merchant Court is a great place to stay in Singapore" Referring to the same entity?

Minimum Edit Distance — Efficiency

• Time:

• Space:

• Backtrace:

Minimum Edit Distance — Efficiency

• Time: *O(nm)*

• Space: *O(nm)*

• Backtrace: O(n+m)

Minimum Edit Distance — Extensions

- Weighted Minimum Edit Distance, e.g.:
 - Spell Correction: some letters are more likely to be mistyped than others
 - Biology: certain kinds of deletions or insertions are more likely than others

→ Generalization of algorithm

■ Application-dependent weights (i.e., costs for edit operations)

Initialization of base cases:

Recurrence relation:

$$\begin{aligned} D(0,0) &= 0\\ D(i,0) &= D(i-1,0) + del(X[i]), & \text{for } 1 < i \le n\\ D(0,j) &= D(0,j-1) + ins(Y[i]), & \text{for } 1 < i \le m \end{aligned} \qquad D(i,j) = min \begin{cases} D(i-1,j) &+ del(X[i]) \\ D(i,j-1) &+ ins(Y[j]) \\ D(i-1,j-1) &+ sub(X[i],Y[i]) \end{cases} \end{aligned}$$

Minimum Edit Distance — Extensions

• Needleman-Wunsch

- No penalty for gaps (*) at the beginning or the end of an alignment
- Good if strings have very different lengths

• Smith-Wasserman

- Ignore badly aligned regions
- Find optimal <u>local</u> alignments within substrings (Levenshtein finds the best global distance and alignment)

Common application: Alignment of nucleotides sequences

Outline

• Regular Expressions

- Basic Concepts
- Relationship to FSA
- Error Types

Corpus Preprocessing

- Tokenization
- Normalization
- Stemming / Lemmatization
- Segmentation

• Word error handling

- Spelling Errors
- Minimum Edit Distance
- Noisy Channel Model

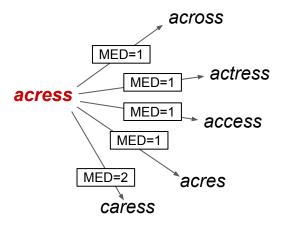

2

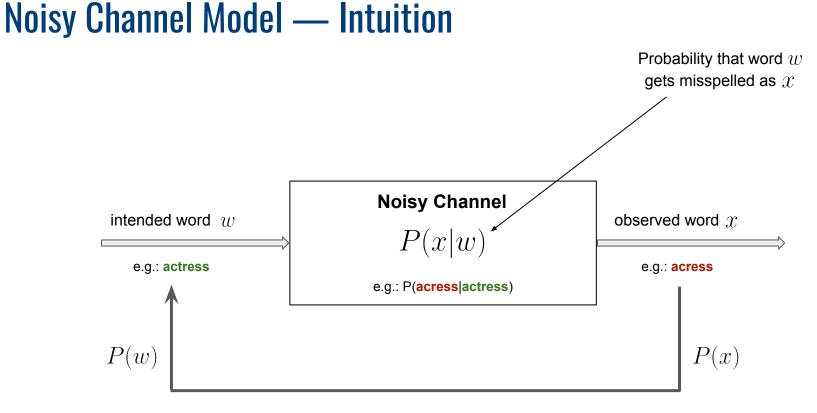

Where We are Right Now

- Given a misspelled word, generate suitable candidates for error correction
 - 80% of errors are within minimum edit distance 1
 - Almost all errors within minimum edit distance 2
 - Covers also missing spaces and hyphens (e.g., thisidea vs. this idea; inlaw vs. in-law)
- Still missing: Which is the most likely candidate?
 - Ranking of candidates to show top candidates first
 - Support for automated spelling correction

➔ Noisy Channel Model

Idea: Assign each candidate a probability

Decoding: Observing error x, can we predict correct word w?

Noisy Channel Model — Bayesian Inferencing

Given an observation $\, x \,$ of a misspelled word,

find the correct word w:

$$\widehat{w} = \operatorname*{argmax}_{w \in V} P(w|x)$$

$$\widehat{w} = \operatorname*{argmax}_{w \in V} \frac{P(x|w)P(w)}{P(x)}$$

$$\widehat{w} = \operatorname*{argmax}_{w \in V} P(x|w) P(w)$$

Quick refresher: Bayes' Theorem P(A, B) = P(A|B)P(B) P(A, B) = P(B|A)P(A) $\Rightarrow P(A|B)P(B) = P(B|A)P(A)$ $\Rightarrow P(A|B) = \frac{P(B|A)P(A)}{P(B)}$

 \rightarrow How to calculate P(x|w) and P(w)?

- Approach using Maximum Likelihood Estimate (MLE)
 - $\blacksquare \;$ Required: Large text corpus with N words

• Calculate/estimate
$$P(w)$$
 with $P(w) = \frac{freq(w)}{N}$

- Example
 - 100 MB Wikipedia dump
 - Total of 14.4M+ words

w	freq(w)	P(w)
actress	1,135	0.0000784
cress	1	0.00000
caress	3	0.00000
access	1,670	0.0001153
across	1,756	0.0001213
acres	177	0.0000122

Note: The frequencies can widely different across different corpora (e.g. Wikipedia articles vs. English Literature).

- In general, P(x|w) almost impossible to predict
 - Predictions depends on arbitrary factors

(e.g., proficiency of typist, lighting conditions, input device)

- Estimate P(x|w) based on simplifying assumptions (Kernighan et al., 1990)
 - Most misspelled words in typewritten text are single-error
 - Consider only single-error misspellings: Insertion, Deletion, Substitution, Transposition

- Definition of 4 confusion matrices (1 for each single-error type)
 - Each confusion matrix lists the number of times one "thing" was confused with another
 - e.g., for substitution, an entry represents the number of times one letter was incorrectly used

• Underlying definitions for generate confusion matrices

ins[x, y]	number of times x was typed as xy
del[x,y]	number of times xy was typed as x
sub[x, y]	number of times x is substituted for y
trans[x, y]	number of times xy was typed as yx
count[x]	number of times that \boldsymbol{x} appeared in the training set
count[x, y]	number of times that xy appeared in the training set

 $x, y \in \{a, b, c, ..., z\}$

$$P(x|w) = \begin{cases} \frac{ins[w_{i-1}, x_i]}{count[w_i]} &, \text{ if insertion} \\ \frac{del[w_{i-1}, w_i]}{count[w_{i-1}, w_i]} &, \text{ if deletion} \\ \frac{sub[x_i, w_i]}{count[w_i]} &, \text{ if substitution} \\ \frac{trans[w_i, w_{i+1}]}{count[w_i, w_{i+1}]} &, \text{ if transposition} \end{cases}$$

 w_i = i-th character in the correct word w

 x_i = i-th character in the misspelled word x

sub[X, V] = Substitution of X (incorrect) for V (correct)

Source: <u>A Spelling Correction Program Based on a Noisy Channel Model</u> (Kernighan et al., 1990)

Noisy Channel Model — Example

• Noisy channel probabilities for "acress"

Candidate Correction	Correct Letter	Error Letter	x w	P(x w)	P(w)	10 ⁹ *P(x w)P(w)	%
actress	t		c ct	.000117	.0000231	2.7	35.9
cress		а	a #	.00000144	.00000054	.00078	~0
caress	са	ac	ac ca	.00000164	.00000170	.0028	~0
access	С	r	r c	.00000021	.0000916	.019	~0
across	0	е	elo	.0000093	.000299	2.8	37.2
acres		S	es e	.0000321	.0000318	1.0	13.3
acres		S	ss s	.0000342	.0000318	1.0	13.3

→ Choice of candidate for correction: *across*

Noisy Channel Model — Discussion

- Basic limitation: No consideration of additional context
 - Model only applicable for non-word errors
 - Basic model will always suggest "across" to correct "acress"

"The role was played by an acress famous for her comedic timing."

→ Language Models (next lecture)

Summary

- RegEx fundamental and useful tool
- Text Preprocessing getting your data ready for analysis
 - Tokenization
 - Stemming / Lemmatization
 - Normalization

typical very task-dependent!

- Error Handling (so far)
 - Focus on single-error misspellings
 - Focus on isolated-word error correction

already very non-trivial!

Student Learning Outcomes

Outlook for Next Week: Language Models

Image from Da Nina @ Unsplash

Pre-Lecture Activity for Next Week

• Assigned Task

Post a 1–2 sentence answer to the following question into the L1 Discussion (you will find the thread on Canvas > Discussions)

> "What do we mean when we talk about the probability of a sentence?"

Side notes:

- This task is meant as a warm-up to provide some context for the next lecture
- No worries if you get lost; we will talk about this in the next lecture
- You can just copy-&-paste others' answers, but his won't help you learn better
